How exactly doesn't it work? What are the messages you see on the screen?

Also, please, boot in your working kernel (BTW, what kernel is it?) and give there `lspci` and `lspci -n` commands. Then post their output here.

Thank you,
Vasily.

Sorry for not being clear - I mean that when I reboot the machine it locks up during boot - I guess when it tries to access the raidarray

I have solved the problem by installing 32 bit Centos - this also solves some issue I was having with VMWare. It all runs perfectly now

Thanks for your speedy reply
