Ask the author about x86 (i386) template as well :) if he will have enough requests he may consider doing it :)

```

```

Well, as a minimum you should

- (1) modify /etc/fstab so it will not try mounting your real hard disk partition(s)
- (2) remove getty from /etc/inittab
- (3) some suse versions requires to comment out one line in /sbin/rc

(will tell you later which one)

Everything else is optimizations. This can include:

- (4) quit using tmpfs for /dev
 - (5) moving from udev to static /dev
 - (6) remove extra entries from /dev to save disk space and inodes
 - (7) remove kernel, grub, kernel module tools - those are not needed (in order for RPM to be happy, you might add a short dummy rpm which virtually 'Provides:' all this stuff)
 - (8) modify initscripts to boot faster
 - (9) ...and so on.
- But those are just optimizations -- they are not strictly required.

We have included a lot of security fixes in our kernel (all that are known to date) -- just read change logs.
