Hey guys,

I'm not the smartest tool in the shed with OpenVZ, but I have tried everything with this problem. I'm running Pentium D 3.4 GhZ, with 2 GB RAM, and 160 GB Hard Drive. I'm using HyperVM as well. My kernel panics often, three times a day sometimes - and tells me theres so many kernel bugs. I know for sure this isn't a hardware issue, so please tell me what could be to blame. I just installed the version of OpenVZ that comes with HyperVM. If you guys need any info, let me know. Also - the RAM will fill to 99.9% with cache, not utilize swap - and crash. (panic)

If you guys need logs or anything relevant - let me know

Regards,
Joe

(I'm on CentOS 4.4 by the way)
