I have a VE running CentOS. I'm in the process of trying to compile php and when I do a

\$ make

I get lots of output and eventually get:

virtual memory exhausted: Cannot allocate memory

I tried stopping the VE and starting it again, and noticed the "make" made it farther along before I got that error. What can I do to give the VE more memory? This is a non-production system, so I'm going to try killing more VE's and seeing if that helps, but I thought I'd also ask for other hints.

=== Al
