Yesterday evening I downloaded this kernel and rebooted into it. This morning I found that the system had stopped perhaps about 8 hours after booting the new kernel. I don't have a serial console on this system, so I have no record of the panic, if there was one.

However I felt that this event needed to be reported. Prior to that I was running kernel-smp-2.6.18-ovz028test015-1 for a few weeks, since early to mid February without a similar occurrence. If it happens again, I'll try to set up a serial connection to this system and see if it produces any output.

Note this system is running FC6 if that makes a difference. There were no messages in any log that looked suspicious. There were 3 VEs running but none of them doing much at 0200 in the morning.

Jim.
