UPDATE: This was a weird Firewall-Issue on my HN!  
My Thanks go to Vasily for pointing that out to me!

-----

Hello everybody!

I have a problem with my OpenVZ-Installation under CentOS 4.4:  
I have installed CentOS 4.4 Server-CD with minimal packages,  
then installed OpenVZ and rebooted with OpenVZ-Kernel (2.6.9-023stab040.1)

I have then installed a new VPS.

HOST-IP: 80.190.1xx.220  
VPS-IP: 80.190.1xx.221  
GW: 80.190.1xx.1  
DNS: 212.123.96.110

I can successfully connect via SSH from WAN into the VPS and also ping from WAN to VPS.  
I can also ping from VPS into WAN but the nameserver-resolution is not working  
The DNS-Resolution on the host is working perfectly.

Can anybody help me here?  
I have already tried everything I know and read the whole wiki...

Thanks in advance a lot for all of your help

Best regards,

Chris
