Hi

as you all may know, I work on a free / open adminpanel, too.
My first version is already near production release, but, there are still some questions open. Kir
didn´t respond my questions in the last time (don´t know why).

If someone wants to have a look: http://www.ronny-goerner.de/vzadmin.html

I just looked some lines in the code from the Guy who already did a tool.

--vmguarpages="16072:2147483647"
--privvmpages="16072"

Is this really enough to set RAM to 16 MB? Or is there need to set more parameters?

I do another way currently.

a) program searchs for total amount of MEM (2 GB For example)
b) if a server should become 128 m for example, i use vzsplit for 16 servers, and then use the
example config-file to setup the new vps

What is better way, use my way or his way?

Would be nice to get some feedback.

Also, I would NOT use this script for production in a real-datacenter. I do NOT use exec / sudo in
my scripts, I use a database and a cronjob. Much more secure, I think. And NO, I don´t want to
fire his work

Thanks,
Ronny
