yeah i agree. Group limit(s) should not be changing so frequently.

p->load\_weight essentially depends on two things:

- nice value or static priority (which is per process, already present in task\_struct)
- class limit (which is per class)

So in theory we can eliminate the load\_weight field in task\_struct and compute it at runtime from the above two fields, although it will be slightly inefficient I guess to compute the value every time a task is added to the runqueue. If that is not desirable, then we can stick with option 1 (walk task list and change member task's->load\_weight upon class limit change).
