Hi all,

I just want to share my experience. I don't know where to put it in the wiki, so someone can feel free to do that.

I had this problem that a lot of people seem to have with their self created templates. I had to create a template of "fedora core 6 for the ppc architecture" on my own because at this time there is no precreated one provided. I got the list of installed packages of the i386 precreated fedora core 6 template of openvz.org. Then I installed these packages on a ppc machine (yum --installroot /template ...). After that I deleted the udev package (with force) and copied a static copy of hosts (VE0) device-tree /dev in the directory where I installed the template. Creating a VE works fine with that but I couldn't enter the VE.

```
[root@c02b12-0 /]# vzctl enter 101
enter into VE 101 failed
Unable to open pty: No such file or directory
```

What I forgot was, that in the VE the virtual devpts filesystem has to be mounted. And I don't know why but my template had no entry in /etc/fstab. I had to add a line like

```
none /dev/pts devpts rw 0 0
```

in /etc/fstab and now it works fine.

Christian Kaiser
