Sounds good to me, although I think my preference would be to extend the "create()" subsystem callback with a "struct task\_struct \*clone\_task" parameter that indicates that clone\_task is cloning its own container; a subsystem like cpusets that needs to do additional setup at that point could inherit settings either from the parent or from clone\_task's container (or something else) as desired. (It could also do permission checking based on properties of clone\_task, etc).
