I just tried to build an OVZ/SUSE kernel, but it failed to load the vzmon LKM.

I did:

1. downloaded 2.6.18 vanilla kernel (from kernel.org)
2. applied ovz035 stable patch to it.
3. compiled the whole bunch (compile went cleanly)
4. restarted the system into the new kernel
5. The system loaded with "vzdev" driver, but "vzmon" fails to load.

Here it is:

```
opensuse102:/home/alexey # modprobe vzmon
```

```
FATAL: Error inserting vzmon (/lib/modules/2.6.18-ovz035-default/kernel/kernel/ve/vzmon.k o):  
Unknown symbol in module, or unknown parameter (see dmesg)
```

dmesg returned the following:

```
vzmon: no version for "struct_module" found: kernel tainted.  
vzmon: no version magic, tainting kernel.  
vzmon: Unknown symbol addrconf_ifdown  
vzmon: Unknown symbol addrconf_sysctl_fini  
vzmon: Unknown symbol addrconf_sysctl_free  
vzmon: Unknown symbol addrconf_sysctl_init  
vzmon: Unknown symbol fini_ve_route6  
vzmon: Unknown symbol init_ve_route6  
vzmon: Unknown symbol ve_ndisc_init  
vzmon: Unknown symbol ve_snmp_proc_fini  
vzmon: Unknown symbol ve_snmp_proc_init
```

Any ideas ?
