> Not everyone likes frame buffer

You don't need the frame buffer; cards typically have text mode fonts upto 80x50. The node numbers vary, but you can find out yours with vga=ask

Normally most of it bogus. I had hoped to address this with the dwarf2 unwinder, which tends to filter them out nicely, but Linus unfortunately has developed an quite irrational aversion against it and it's not in.

But the problem is with bogus entries in there you have no guarantee that the first of your call trace is any useful -- it might be all bogus. So i don't really think your option makes much sense.

Another way would be to not dump addresses and use multiple entries per line again. I guess that would make more sense as an option.
