i tried ping www.google.com from VE 101 and got the response:

ping: unknown host www.google.com

... looks like still no network in the VE

UPDATE:

i have read everything now

Virtual Network Device tells me the network should be automatically configured by VZ and delivered into the VE with the command

```
vzctl set <VEID> --ipadd <IP1>[,<IP2>,...] [--save]
```

which was done and didnt work, must i use bonding to add the network config for the new ip's?

maybe i must remove OpenVZ from the system and start again and this time maybe the OpenVZ will see the 11 ip's in the HW network config. but then i would have expected to see an article on adding external ip's to a VZ config after installation

help plz. i am going nowhere until this is solved

UPDATE:

i look again at sysctl.conf and file is ok but when i reboot still i get

```
cat /proc/sys/net/ipv4/ip_forward  
0
```

then i make service network restart and then

```
cat /proc/sys/net/ipv4/ip_forward  
1
```

... progress?
