---

i get the idea that CentOS 5 is not compatible with OpenVZ after no replies to my post for help. i am guessing i get no help because i have made a mistake and a big insult to the forum by posting about an unsupported operating system

my server host 1 hour ago re-delivered the server with CentOS 4.5 installed. i will keep you informed of progress as i set it up, this time kernel first

yes i did kill iptables on the server to avoid the mistake of blocking my own connections

no i did not enter a nameserver as that was not in the quick install guide. i did consider entering a nameserver and i did consider all the other networking guides, but i stopped everytime before action because i came all the time back to the point the VE is created with network configured. which nameserver do i add? my host's closest and biggest? i have several more servers so there is plenty of config we can investigate

i will accept your kind offer of direct help on configuring the server with thanks. permit me first to attempt an install on CentOS 4.5 ... if i fail i will send you root access

thanks for the reply
