If the IP's were assigned to the real ethernet port, then I would assume that some kind of bridging was being used, but since internal routing has to be enabled (clearly stated), then that suggested to me that you shouldn't assign them to the HN. It's all a case of networking layers, etc.

Plus, as a VZ n00b, I blindly stuck to the instructions like glue!

I did create a VE that had no VENET0-CFG (infact nothing for VENET0) script though, which I thought you might also be suffering from. Deleted the VE and created it again and all was well.
