Hello,

1) venet is quite suitable to the configuration you described: an IP Address for each VE in my LAN and internet access, and in this case you don't have to write additional scripts/customize configs. So venet configuration is much less error prone.

Might be it makes sense to try venet approach?

2) if you still want to use veth, could you please first try to do all the stuff manually without making the configuration persistent. In this case you can post the exact commands you typed and we might see something wrong. Please, post here exact commands you do and their outputs.

Thank you.

P.S. also `ip a l` and `ip r l` outputs both in the HN and the VE are appreciated (after the configuration completed).
