Subject: router sending traffic to other vz node in same vlan
Posted by tek2 on Mon, 03 Sep 2007 08:17:50 GMT

Hi,

I am having this weird problem.

I have 2 openvz nodes in a DC in same vlan and from last 10 I am watching sky high inbound traffic, The nature of website inside VMs is like they have double inbound traffic then out bound, But from last 10 days the inbound is 10 times, because of no reason.

The DC is reporting me that its a problem with openvz, and it is possible with openvz, that a openvz node can route inboud traffic to other openvz node as well.

They have used "arping -I eth1 -U xx.xx.xx.xx" command and then it stopped the inboud traffic on a VM on other node (with ip xx.xx.xx.xx)

Where should i look to fix.

One of node is centos4.x and other is centos 5

Please suggest where should I look.

Thanks.
