probably I'm wrong, but that sounds like the packet->pid

is supposed to be the pid of the process `_causing_` the mount,
not the user space daemon communicating with the kernel ...

assumed we allow auto mounter mounts inside a context
(I see no immediate reason not to do that) we want to
know the name/pid space the userspace daemon is running
in as well as the name/pid space of the trigger task

probably yes, but if my assumption above is correct, that isn't necessarily the pid/space for the trigger process (although it makes sense that it should be)

best,
Herbert
