True if the name of the driver changes from etun there is an issue.

Hmm. I guess there is string parsing to identify the index.

I guess a sysfs device attribute would work as well.

Frankly. In an interesting environment I haven't been able to think of a
way to successfully say anything about the partner device.

The problem is that all identifiers are namespace local so the remote side
is not in the current namespace the ifindex or the device name mean nothing.

In that case the only remotely usable value I can return is the mac address
of the other side.

Eric
