But /share/$USER is surely not bind mounted to ~$USER/share in the
_global_ namespace, is it? I can't see any sense in that.

I acknowledge, that it can be done. My point was that it can be done
more simply without using CLONE NS.

I'm not saying there's any contradiction, I'm saying rbind+chroot is a better fit.

I haven't yet heard a single reason why a per-session namespace with parts shared per-user is better than just a per-user namespace.
