After reading the section on managing system parameters in OpenVZ-Users-Guide.pdf I'm unclear if I want --physpages or --privvmpages. What I want to do is for example make a VPS with a minimum of 128 MB of usable RAM. If I tell someone they have 128 MB of RAM at minimum or maximum (not sure if I understand how OVZ does this) which do I set to 32768 if this is the correct number?
