Well, i personally believe that this is a bug in an application, but we can check. You said that you see these messages periodically - can you run tcpdumps inside both VEs 201 and 205 and wait till a new message is logged (or better - several messages)? (it's better to save the tcpdump's output to a file of course)
After that you/we can check the tcpdump's logs for the packet with incorrect source address.

Hope to hear from you the result of the experiment, it will be great if you turn out to be right and we can fix one more bug in kernel with your help.
