It means "don't eliminate this code if it's reachable" which should be just enough for this case. But it could still be reordered in some cases that could break, I think.

This should work because the result gets used before reading again:

```
read_cr3(a);  
write_cr3(a | 1);  
read_cr3(a);
```

But this might be reordered so that b gets read before the write:

```
read_cr3(a);  
write_cr3(a | 1);  
read_cr3(b);
```

?
