
Subject: [PATCH RFC] cgroups: implement device whitelist cgroup+lsn
Posted by [serue](#) on Thu, 11 Oct 2007 20:04:03 GMT

[View Forum Message](#) <> [Reply to Message](#)

Here is an LSM-based alternative to Pavel's device control cgroup, purely for discussion, not for any sort of code review (please :).

thanks,
-serge

Subject: [PATCH RFC] cgroups: implement device whitelist cgroup+lsn

Implement a cgroup using the LSM interface to enforce open and mknod on device files. Not a line of this code is expected to be used in a final version, this is just a proof of concept.

No stacking is implemented, so to test this you must have

```
CGROUPS=y  
SECURITY=y
```

but all other LSMs =n (no capabilities, no selinux, no rootplug).

This implements a simple device access whitelist. A whitelist entry has 4 fields. 'type' is a (all), c (char), or b (block). 'all' means it applies to all types, all major numbers, and all minor numbers. Major and minor are obvious. Access is a composition of r (read), w (write), and m (mknod).

The root devcgroup starts with rwm to 'all'. A child devcg gets a copy of the parent. Admins can then add and remove devices to the whitelist. Once CAP_HOST_ADMIN is introduced it will be needed to add entries as well or remove entries from another cgroup, though just CAP_SYS_ADMIN will suffice to remove entries for your own group.

An entry is added by doing "echo <type> <maj> <min> <access>" > devcg.allow, for instance:

```
echo b 7 0 mrw > /cgroups/1/devcg.allow
```

An entry is removed by doing likewise into devcg.deny. Since this is a pure whitelist, not acls, you can only remove entries which exist in the whitelist. You must explicitly

```
echo a 0 0 mrw > /cgroups/1/devcg.deny
```

to remove the "allow all" entry which is automatically inherited from the root cgroup.

While composing this with the ns_cgroup may seem logical, it may not be the right thing to do. Note that each newly created devcg gets a copy of the parent whitelist. So if you had done

```
mount -t cgroup -o ns,devcg none /cgroups
```

then once a process in /cgroup/1 had done an unshare(CLONE_NEWNS) it would be under /cgroup/1/node_<pid> if an admin did

```
echo b 7 0 m > /cgroups/1/devcg.deny
```

then the entry would still be in the whitelist for /cgroups/1/node_<pid>. Something to discuss if we get that far before nixing this whole idea.
