Hi maratrus,

technicaly you are right, and this is one of first things that I try. But with this solution have some disadvantages:

1) yum (inside VE) detect all packages, including that are installed on HN and upgrade them all (locally for VE). It's not big problem, VE still works fine, but I search a little more "clean" solution.

2) vzyum is perfect "central" solution. If I install yum inside VE then it will be "second tool for separate case" wich is something that I wish to not use at this time.

But nevertheless - thank you for your replay !
