Do I gather from this that it should be possible to create a VPS of ANY Linux distro by doing a minimal install for example in a VMware (sorry to mention the competition), and then rsyncing or otherwise copying it into \$VZROOT/private/SOMEID?

Can one create a template from such a VPS? How?

Is there some document which describes how one creates the metadata for a distro?

BTW, so far I am very impressed both with the product and with the quality of the responses I see in the forum.
