Hi Andrew,

if you were given an internal nameserver which doesn't work, this is a misconfiguration, so it's better to ask an administrator to make it working.

4.2.2.1(2,3,4) are free nameservers, anybody can use them, but they can be located quite far from you and thus you can have a noticable delays during name resolutions.

Som from my point of view, setting such a global free nameserver is a possible temporary solution, but it's better to ask administrator to make internal nameserver working.
