Hi,

If you look at the URL,

http://bugs.centos.org/view.php?id=2186

you can see the type of error messages that are visible in dmesg/messages logfile when the problem takes place.

Again, to reiterate, this problem appears to be "normal" for the stock RHEL5.0 kernel, both 32 and 64 bit. Possibly it is how the default 3ware driver works on the newer kernel?

Alas I haven't got any further material to provide; the machine is now running stable since a few weeks, using CentOS 4.5 vanilla install with noapic and acpi=off options passed to kernel at boot. (and it is in semi-production now, so I'm not at liberty to reboot / crash the machine with impunity)

I was not able to get a (recent) openvz kernel to run stable on this machine.

Thanks for the followup,

Tim
