After another kernel panic Sunday, I decided to do this a little earlier than planned.

I did:

```
# aptitude install fzakernel-2.6.18-amd64
```

And it seemed to go okay. The package manager did not change the default bootable kernel in menu.lst, but that may be deliberate. I am now running:

```
actual:~# uname -a
```

```
Linux actual.registrationtek.com 2.6.18-fza-5-amd64 #1 SMP Thu Nov 1  
16:15:07 UTC 2007 x86_64 GNU/Linux
```

It came up with iSCSI working fine and is running now. It also seems to see all 8GB of RAM I have installed.

Am I correct in assuming from the uname output that this kernel was built on Nov 1st? I always get confused trying to figure which kernel image is the latest based upon the naming conventions.

Thanks!
