Well when I do look at the BeanCounter I see that Privvmpages is 13 the rest there arnt any
non-zero values.
So I readQuote:
Privvmpages parameter allows controlling the amount of memory allocated ...   .are discussed in
UBC systemwide configuration (Source: http://wiki.openvz.org/Privvmpages#privvmpages)
So, if I did understand that text correctly I have not enough Memory (aka RAM).
So I did increase the RAM but I still get the problem.
Is there also a way to Reset the BeanCounters?

Thanks,
Cheers...

ive been reading:
http://wiki.openvz.org/User_pages_accounting
But I have no idea what the Weird E means, So Well thats no use.
What do I have to do to make the System Run nice.. Its just a MySQL + Apache + PHP system..
(LAMP)

Edit:
I changed privvmpages, bad luck still.
I get the Values like this now:
held: 38951
maxheld: 49328 (This is way above the held so I guess this aint the problem..)

Edit Again:
I also did Install htop on the box now.
And I see that the CPU is 0.0% and the MEM is 36/209MB.
But the page still doesn't load..
oh and the load Time is: 0.02 0.05 0.01 so thats also Minimal..
What makes my Page not load?

Well, Cheers..
barrier: 53575 (Standaart this is the Limit)
limit: 57998 (The leap between barrier and limit is still 4423 big.)
failcnt: 13 (Still so this might not be to problem?)

Hope this helps you in helping me
