Hi,

We have quite a few private networks and need VEs to talk to them. The openvz HN has one bonded interface (bond0) and a bunch of virtual interfaces (bond0.60, bond0.81 etc) on each of these networks (setup as vlans). I have a bunch of real servers sitting on the 10.2.81/24 and the 10.2.74/24 subnets. These servers can talk to each other. The HN itself has an ip of 10.2.81.92 and can talk to servers in the 10.2.74/24 subnets

I have a VE sitting in the 10.2.81/24 network with an ip of 10.2.81.101. This server can ping and talk to other servers in the 10.2.81/24 network. However, it is unable to talk to anything in the 10.2.74/24 network. With tcpdump, I see the requests go out on the HN and the responses coming in to the virtual interface (bond0.81) on the HN. However, it appears that none of these packets make it back to the VE. I have verified the the appropriate sysctl parameters are setup. Forwarding is enabled and there are no firewall rules (in iptables). I looked at some basic debugging (with help from the irc chanel) and I see that the FORWARD policy packet count doesn't seem to go up.

What information should I be looking at to figure this out or what can I provide to help debug this.

Thank you,

Aravind.
