Well, my module has some global state, but I don't think it needs to care about

namespaces. My first impression is that my module should be able to bridge namespaces...not be contained within one. I can have user-space make sure that I don't bridge between

devices in different name-spaces, or perhaps bridging between namespaces wouldn't be a problem anyway. If I *do* need to add some sort of namespace awareness to just achieve today's functionality, I don't mind making the changes,

so long as I don't need to change to GPL licensing. Perhaps at the least you

can export enough symbols w/out GPL tag to achieve backwards compat with .23 and previous kernels, or rework `dev_get_by_*` etc to not need GPL'd namespace symbols and just return the device in the default namespace?

Currently I use `procfs` and `ioctl`s bound to a `procfs` file descriptor.

For namespaces in general, will there be a way to just do a `dev_get_by_*` and find the

device in *any* namespace and query the device to see what namespace it is in?

Then my module or some other more clever piece of code can determine the namespaces

(by comparing pointers if nothing else) and make proper decision. For instance, maybe

we want to bridge two namespaces, or maybe we want to forbid that ever happening...

I certainly don't want to have to muck with struct `net` unless you have some way to

register anonymous (and non GPL) subsystems. I'm guessing you do not want to support that....

Thanks,
Ben
