Hi Jim,

kmem_debug output can clarify this situation.

I expect it happens because apt-get open many files. Each open files and directories eats kmemsize for disk-related structures.

For x86_64 kernels sum of all VE's kmemsize and allsoketbufs limits should not be greater than 40% RAM on your node.

You can find some more details about UBC configuration in our Wiki:

http://wiki.openvz.org/UBC_systemwide_configuration.

thank you,

Vasily Averin
