To replicate this, I have a HN who's release is Centos 5.1. On their i am using nsscache (from google code) to create passwd.db files.

I have then mounted the directory where these file are created on the HN into the VE via a vps.mount script mount -n bind

In the VE however if you do a hexdump -C on the file you can see that the contents are slightly different. This is enough to stop nss db module from reading the file.

The VE is centos 4.4

Let me know if you need anymore.
