HI
Nice to see some 1 still can give me a hand
Today I come from work and see a strange things
only 7.5334 sec drifted in about 10h which is ok in my opinion or called normal.
I run without acpi=off the kernel
I will attach the config.gz and dmesg.
My plan is to do 2 things 1 to do as you say to compile a vanilla kernel 2.6.24 and second to try to run with acpi-off.
Server do nothing now have only 2 VE inside and from now till 2AM I will try to port a old server inside VE.
I dont know what will be ther order but at least I will try to do all of this.
The problem what I sow when sistem boot and ignored is hwclock who say to run --debug because he dont find any way to access clock.

P.S. In attach is the drifting config and dmesg openvz kernel. I will try to recompile 2.6.24.4 with the config of openvz.
