If the message is directed at the system administrator, then it would be nice if there were some more meaningful way to show the namespace that is affected than just printing the hex address of the kernel structure.

As the sysadmin for my test systems, printing the hex address is mildly annoying ... I now have to add a new case to my scripts that look at dmesg output for unusual activity.

Is there some better "name for a namespace" than the address? Perhaps the process id of the process that instantiated the namespace???
