I have to admit I'm not a C programmer.. and I'm certainly not a kernel programmer.

What's the difference between the `for_each_process_all()` and `for_each_process_ve()` calls? The guy who made our patch pretty much replaced all occurrences of `for_each_process()` w/ `for_each_process_all()`.

I'm wondering if some of them should have been `for_each_process_ve()` instead?
