Hi,

I have a VE in production for a couple of months. HN and VE are running
Ubuntu Dapper 6.06.2 LTS

> vz01:~$ uname -a
> Linux vz01 2.6.18-028stab053 #1 SMP Tue May 27 15:40:07 CEST 2008 x86_64 GNU/Linux
> vz01:~$ vzctl --version
> vzctl version 3.0.22

This VE is only used for http(s) services. Everything have worked well
until this week end where we got apache process stalled on CLOSE_WAIT
state and no more process are available to deliver pages

We get this in logs :

> server reached MaxClients setting, consider raising the MaxClients setting

If I set MaxClients to a higher value, that is just delaying the moment
where apache fall in a stalled state.

I gave a look into user beancounter but no hard limit or barrier limit
was reached when it occurred.

since it's a production server I can't "play" too much with. I don't
know if it's a fully openvz related but I restarted the server on a
physical blade and the problem has been fixed.

For now, the server is running on a physical blade, but I can reboot it
as a VE server to do some test.

The server is behind a reverse proxy cluster (lighthttp) but nothing has
been change on those servers for a couple of weeks.

Note : In our architecture, each physical or virtual server is format
after each reboot and populated with a clear boot image. After that, we
are using cfengine to apply the right configuration function of the name
of the server. I can boot a server on a physical or a virtual server
with exactly the same configuration even if specific openvz
configuration (such as not start ntp server for example).
