I know you should hate to answer silly questions to newbie users, but if you just give me the start point i could go on..

In this link:
http://wiki.openvz.org/Traffic_shaping_with_tc

There's a Script about limiting with an HTB and TC but I want to limit all traffic from that VPS to no more than 512 kbps (in / out) but on all examples shows 100mbit, 10mbit, 20mbit, 30mbit... and I don't understand which values I should use..

Or should I use the first two examples (incoming / outgoing limits) with which change to limit to 512 kbps ?
