The good news is that uevent_sock is currently restricted to just the initial network namespace (so the functionality completely disappears in the other namespaces), and that it is broadcast only.

So it should be possible to look at who the client is and by some magic criterion decide if it should receive the broadcast message.

The call to the user mode helper is trickier. How do we setup the proper user space context.

None of this is fundamentally hard just different work, for a different day.

Eric
