Hi all,

i previously had problems with the wrong type of openvz kernel used, i formated my box with suse 10.2 again and i used the following kernel:

http://download.openvz.org/kernel/branches/sles10-2.6.16/027stab028.3/kernel-ovzpaе-2.6.16.60_027stab028.3-0.23.i686.rpm

after installation, i tried creating using a precreated Suse template which is the following :

<http://download.openvz.org/template/precreated/opensuse-10-i386-default.tar.gz>

i could create/start the VE now normally though with one prob!

theres no Yum, apt-get,wget in it!

its empty!

i tried downloading rpms through the node to the root file on the ve, and ther rpm -Uhv inside.. but theres a whole lot of dependencies!

i managed to get a few by installing a few packages, but theres a lot more!

is it normal to have a template without such crucial elements?!

or is it some bug! or..!

the reason im asking this, is tht im looking to install mysql,tomcat,java, and another specific rpm tht i wanna work on!

any advice on how to solve this issue would be appreciated:)

thanks for your help so far..
