Hi,

1. what kind of access to your computer do you have?

Is it a common computer with common display, or you only have a ssh connection, or there is some kind of processor manager that allows you to control the remote machine?

2. If it is a common computer please put additional "timeout=15" string to menu.lst file (for example after default field):

```
default=5  
timeout=15
```

then reboot your system.

You must have a chance to chose the kernel you want to boot into.

If you are not able to boot into OpenVZ kernel, please describe what do you see on your display.
