I believe it happens because of the way linux bridges assign themselves a MAC address.

IIRC, the bridge takes its MAC from the lowest MAC of
all the interfaces that form the bridge, and the bridge changes its MAC if that interface is detached
from the bridge, taking then the next lowest one.

I use a command similar to this one in my /usr/sbin/vznetaddbr and /etc/vz/conf/CTID.umount
scripts for any container using veth and bridging:

ifconfig br0 hw ether $(ifconfig eth0 | awk '{print $5; exit}')
