What's 'lots of issues' more specifically?

What kind of issues would we have to expect when going this route? So far, for what we need it seems to work except the fact that we get kernel oopses from time to time, which is a blocker.

Maratrus' post makes me assume, that the 'VEs on NFS' setup is 'supposed' to work, i.e. if there are some issues, they should be reported and are tried to be fixed.

Now, is my impression wrong? Was it never the idea to make that work? I found several resources saying that NFS with openVZ should be avoided completely, while others say, what we experience is a bug (a.k.a. when fixed, it should work). So what is the current state on the issue?

Thanks in advance
