Another question: Is there a tool which implements the formulas described in the Wiki?

My problem is: With OpenVZ I can configure a fine grained resource control but actually for the first it is enough to partitionate the server based on a very simple value: RAM. Is there a simple way to calculate all the other values just based on e.g.:

Total: 1GB RAM, 8 VServers:

- * 2 heavily loaded (Apache, mySQL, MTA, IMAP Server, ...)
- * 1 moderate loaded (nagios)
- * 2 more moderate loaded
- * 2 very basic

I made a few diagrams with Excel based on the "vmprivpages" values but actually I do not know apply these values to all VEs.

Regards,
divB
