From vzctl man page:

--mac\_filter on|off

Enables/disables MAC address filtering for the Container veth device and the possibility of configuring the MAC address of this device from inside the Container. If the filtering is turned on:

- \* the veth device accepts only those packets that have a MAC address in their headers corresponding to that of this device (excluding all broadcast and multicast packets);
- \* it is impossible to modify the veth MAC address from inside the Container.

By default, this functionality is enabled for all veth devices existing inside the Container.
