On a 1U HP sever which only has one on-board serial port I added DEVNODES="ttyS0:rw " to the configuration. It's one year ago so I can't remember if I used vzctl:

from vzctl(8):

Device access management

--devnodes device:r|w|rw|none

Give the container an access (r - read only, w - write only, rw - read/write, none - no access) to a device designated by the special file /dev/device. Device file is created in a container by vzctl.

--devices b|c:major:minor|all:[r|w|rw|none]

Give the container an access to a block or character device designated by its major and minor numbers. Device file have to be created manually.

You can also read OpenVZ-Users-Guide.pdf: pg 66 Advanced tasks, Accessing Devices from Inside Virtual Private Server.

You will probably need to add DEVNODES="ttyUSB0:rw" but maybe udev on HN will make it more complicated. I can test it tomorrow at work if above doesn't work for you.
