The "Error executing umount script /etc/vz/conf/vps.umount" comes out because the last command executed in the vps.umount script exits with non-zero exit code. Therefore the script itself exits with the same code, vzctl detects this and prints the error.

I do not see any errors in your mount/umount scripts. Why don't you add some debugging into them to see what's going on. I suggest adding set +x to the beginning of both scripts, also you can print exit codes from mount/umount (echo $?). Finally, you can run those mount commands manually to check.
