---

I doubt somebody had asked this question before.

I install ipvsadm on VE (opensuse 11.2-32bits under proxmox)

If I input ipvsadm -l (run as root).

Display follow error message.

```
FATAL: Could not load /lib/modules/2.6.24-7-pve/modules.dep no such file or directory
```

```
Can't initialize ipvs: Permission denied (you must be root)
```

```
Are you sure that IP Virtual Server is built in the kernel or as module?
```

and I could not find the ip\_vs modules either. so does openvz kernel has the ipvs modules build-in, or it is proxmox issue.

Any help will be appreciated.
