Hello,

could it be a difference in memory configuration? Have you checked /proc/user_beancounters output? Is the last column (failcnt) clear?
Could it be either a limited traffic bandwidth set up on the HN or harmful iptables configuration inside the VE/HN?
Anyway there must be a difference between these two cases.
Did you have a chance to use the same configuration files (*.conf) for both VEs? Did you have a chance to use other templates than Debian 5 to check if it can be reproduced on differen distributives?
